

Task 1. (ex1.py)

$$A_1 = 00 \quad A_2 = 01 \quad A_3 = 10 \quad A_4 = 11 \quad A_5 = 100 \quad A_6 = 101$$

$$M = \begin{matrix} A_1 & A_2 & A_3 & A_4 & A_5 & A_6 \\ 00 & 01 & 10 & 11 & 100 & 101 \end{matrix}$$

Redundant message M

$$\begin{matrix} A_1 & A_2 & A_3 & A_4 & A_5 & A_6 = \\ 000 & 001 & 101 & 110 & 1001 & 1010 \end{matrix}$$

$$A_1 = 000 \quad 0+0=0 \quad 0 \bmod 2 = 0$$

$$A_2 = 011 \quad 0+1=1 \quad 1 \bmod 2 = 1$$

$$A_3 = 101 \quad 1+0=1 \quad 1 \bmod 2 = 1$$

$$A_4 = 110 \quad 1+1=2 \quad 2 \bmod 2 = 0$$

$$A_5 = 1001 \quad 1+0+0=1 \quad 1 \bmod 2 = 1$$

$$A_6 = 1010 \quad 1+0+1=2 \quad 2 \bmod 2 = 0$$

Results from ex1.py

Redundant message M: ['000', '011', '101', '110', '1001', '1010']

Task 3

Redundant codes are useful in cryptographic systems to enhance error detection and correction, making them valuable for secure communication over unreliable channels. They improve the stability of information transmission by allowing the receiver to identify and correct errors, ensuring data integrity. Redundancy is crucial for scenarios where stable transmission is essential, like in noisy environments or long-distance communications.

Non-redundant codes, on the other hand, are appropriate where efficiency is prioritized, such as in environments with low error probability or when computational overhead needs to be minimized. They are best used when the communication channel is reliable, and data integrity checks are either unnecessary or handled by other means.
